## Abstract

Abstract of this course

## 1 Revision

## 2 Perturbation Theory

### 2.1 Time-Independent Perturbation Theory

#### 2.2 First-order Perturbation Theory

$$E_n \simeq E_n^{(0)} + \langle n^{(0)} | \hat{H}^{(1)} | n^{(0)} \rangle$$

$$|n\rangle \simeq |n^{(0)}\rangle + \sum_{m \neq n} |m^{(0)}\rangle \frac{\langle m^{(0)} | \hat{H}^{(1)} | n^{(0)} \rangle}{E_n^{(0)} - E_m^{(0)}}$$

#### 2.3 Second-order Perturbation Theory

$$E_n^{(2)} = \sum_{m \neq n} \frac{|\langle m^{(0)} | \hat{H}^{(1)} | n^{(0)} \rangle|^2}{E_n^{(0)} - E_m^{(0)}}$$

Example: Infinite square well with central bump

... Example: Infinite square well in an electric field

... Example: Harmonic Oscillator + Linear perturbation

... Example: Van der Waals Interaction

...

#### 2.4 Degenerate Perturbation Theory

Example: Perturbed 2D infinite square well

...

#### 2.5 Variation Method

Example: Hydrogen atom ground state energy

...

##### 2.5.1 Rayleigh-Ritz Method

Example: Hydrogen atom with finite proton mass

...

## 3 Wigner-Eckart theorem

Let  $\hat{K}$  be a scalar operator with respect to an angular momentum operator  $\hat{\mathbf{J}}$  :

$$[\hat{\mathbf{J}}, \hat{K}] = 0$$

Then the Wigner-Eckart theorem states that matrix elements of  $\hat{K}$  taken between total angular momentum eigenstates  $|\alpha'' j'' m''\rangle$  and  $|\alpha' j' m'\rangle$  must be of the form

$$\langle \alpha'' j'' m'' | \hat{K} | \alpha' j' m' \rangle = C(\alpha'' \alpha'; j') \delta_{j'' j'} \delta_{m'' m'}$$

where  $C(\alpha''\alpha'; j')$  is a complex constant known as the reduced matrix element which is independent of the quantum numbers  $m''$  and  $m'$ . The quantities  $\alpha''$  and  $\alpha'$  collectively label all other quantum numbers needed to uniquely identify the angular momentum eigenstates involved.

### 3.1 Consequence of Wigner-Eckart theorem (Scalar Hamiltonian)

Since  $\hat{H}$  and  $\hat{J}$  commute, they possess a simultaneous set of eigenstates  $|\alpha jm\rangle$ , where " $\alpha$ " represents all other quantum numbers needed to uniquely identify a particular energy eigenstate of  $\hat{H}$ . From the Wigner-Eckart theorem, the matrix elements of  $\hat{H}$  between these eigenstates must be of the form

$$\langle \alpha'' j'' m'' | \hat{H} | \alpha' j' m' \rangle = \langle \alpha'' j'' || \hat{H} || \alpha' j' \rangle \delta_{j'' j'} \delta_{m'' m'}$$

where the reduced matrix element  $\langle \alpha'' j'' || \hat{H} || \alpha' j' \rangle$  is a constant, independent of the quantum number  $m$ . In particular, the expectation values of  $\hat{H}$  are

$$\langle \alpha jm | \hat{H} | \alpha jm \rangle = \langle \alpha j || \hat{H} || \alpha j \rangle$$

The Wigner-Eckart theorem for scalar operators, Equation, to be written in the form

$$\langle \alpha'' j'' m'' | \hat{K} | \alpha' j' m' \rangle = \langle \alpha'' j'' || \hat{K} || \alpha' j' \rangle \langle 00; j' m' | j'' m'' \rangle.$$

The reason for writing the Wigner-Eckart theorem in this way will become clear once we have also considered the equivalent result for vector operators.

### 3.2 consequence of Wigner-Eckart theorem (Vector Operators)

Then the Wigner-Eckart theorem states that the matrix elements of  $\hat{V}$  between eigenstates  $|\alpha' j' m'\rangle$  and  $|\alpha'' j'' m''\rangle$  of  $\hat{J}$  must be of the form

$$\langle \alpha'' j'' m'' | \hat{V}_m | \alpha' j' m' \rangle = \langle \alpha'' j'' || \hat{V} || \alpha' j' \rangle \langle 1m; j' m' | j'' m'' \rangle,$$

where the final factor,  $\langle 1m; j' m' | j'' m'' \rangle$ , is a Clebsch-Gordan coefficient which can be obtained by considering the angular momentum combination  $j'' = 1 \otimes j' = j', j' \pm 1$

## 4 Electromagnetism

*Definition cyclotron frequency:*

$$\omega_c = \frac{qB}{m}$$

This is the frequency with which particles moving transverse to a magnetic field  $B$  undergo circular orbit.

$\omega_c$  should be really close to the spin precession frequency  $\omega_s$ .

### 4.1 Aharonov-Bohm Effect

### 4.2 Gauge Invariance

#### 4.2.1 Coulomb Gauge

#### 4.2.2 Symmetric Gauge

### 4.3 Orbital Magnetic moment

In Hamiltonian, the  $L \cdot B$  term can be written as:  $\hat{H} = -\hat{\mu}_L \cdot B$  *Definition Orbital magnetic moment operator:*

$$-\hat{\mu}_L = \frac{q}{2m} \hat{L} \gamma_L$$

... *Definition Gyromagnetic ratio,  $\gamma_L$ :*

$$\gamma_L = \frac{q}{2m}$$

... For an electron ( $q=-e$ ), the orbital magnetic moment operator is

## 4.4 Magnetic Moments

### 4.4.1 Electron

### 4.4.2 Muon

### 4.4.3 p, n, nuclei

## 4.5 Spin

### 4.5.1 Particle magnetic moment: spin-half

### 4.5.2 Spin Precession

### 4.5.3 Spin-half

### 4.5.4 Energy Eigenstates

### 4.5.5 Wave-function Evolution

## 4.6 Stern-Gerlach

## 4.7 Landau Levels

### 4.7.1 Landau Gauge

Example: 2D Electron Gas

# 5 Real Hydrogen Atom

## 5.1 Relativistic Corrections

## 5.2 Fine Structure

## 5.3 Hyperfine Structure

# 6 Symmetries

## 6.1 Symmetry Transformation

### 6.1.1 Time translation

Take away: The time-dependent Shrodinger equation is a consequence of the invariance under time transformation

## 6.2 The Wigner-Eckart Theorem(selection rule)

**Wigner-Eckart Theorem:**  $\langle \alpha'' j'' m'' | \hat{K} | \alpha' j' m' \rangle = \langle \alpha'' j'' | \hat{K} | \alpha' j' \rangle$

A particular case is that  $\langle \alpha j m | \hat{K} | \alpha j m \rangle = \langle \alpha j | \hat{K} | \alpha j \rangle$

i.e. the expectation values of a scalar operator are independent of  $m$  and are given by the appropriate reduced matrix element of  $K$

### 6.3 Combining magnetic moment

## 7 Identical Particles

Identical particles are indistinguishable.

1. The normalized two-particle wavefunction  $\psi(x_1, x_2)$ , which gives the probability  $|\psi(x_1, x_2)|^2 dx_1 dx_2$  of finding simultaneously one particle in the interval  $x_1$  to  $x_1 + dx_1$  and another between  $x_2$  to  $x_2 + dx_2$ ,
2. only makes sense if  $|\psi(x_1, x_2)|^2 = |\psi(x_2, x_1)|^2$ , since we can't know which of the two indistinguishable particles we are finding where.
3. It follows from this that the wavefunction can exhibit two (and, generically, only two) possible symmetries under exchange:  $\psi(x_1, x_2) = \psi(x_2, x_1)$  or  $\psi(x_1, x_2) = -\psi(x_2, x_1)$ .<sup>2</sup>
4. If two identical particles have a symmetric wavefunction in some state, particles of that type always have symmetric wavefunctions, and are called bosons. Similarly, particles having antisymmetric wavefunctions are called fermions.
5. We could achieve the necessary antisymmetrization for particles 1 and 2 by subtracting the same product wavefunction with the particles 1 and 2 interchanged, i.e.  $\psi_a(1)\psi_b(2)\psi_c(3) \mapsto (\psi_a(1)\psi_b(2) - \psi_a(2)\psi_b(1))\psi_c(3)$ , ignoring the overall normalization for now. Such a sum over permutations is precisely the definition of the determinant. So, with the appropriate normalization factor:

$$\psi_{abc}(1, 2, 3) = \frac{1}{\sqrt{3!}} \begin{vmatrix} \psi_a(1) & \psi_b(1) & \psi_c(1) \\ \psi_a(2) & \psi_b(2) & \psi_c(2) \\ \psi_a(3) & \psi_b(3) & \psi_c(3) \end{vmatrix}$$

### 7.1 Space and spin

### 7.2 Spin and statistics (fermions and bosons)

### 7.3 Exchange forces

### 7.4 The Helium atom

## 8 Multi-electron atoms

### 8.1 Periodic table

### 8.2 LS coupling (Hund's rule)

### 8.3 jj coupling

## 9 Zeeman effect/Stark effect/Molecules: $H_2^+$ and $H_2$

## 10 Time-dependent perturbation

## 11 Fermi Golden Rule
